

Care guide

Green-bellied Huntsman, *Typostola barbata*

Green-bellied Huntsmen are among Australia's largest spiders, growing up to body length of over 40 mm and a leg span of over 150 mm. They are found from Victoria up the eastern coast of Australia to north QLD. They feed on a wide range of other invertebrates including moths, crickets, cockroaches and other spiders. They have also been known to feed on small vertebrates such as frogs and geckos in the wild.

These spiders are extremely fast, and have the ability to run sideways and squeeze into very narrow crevices. They are covered in fine sensory hairs which are extremely sensitive to air movement. This assists them in detect the movement of prey and the approach of predators.

Like other huntsmen, this species lays its eggs encased within a flattened white silk egg sac. They usually secure this in a dark place such as under loose tree bark and stay with their eggs until after they hatch. The young emerge 30 - 60 days after being laid (they will develop faster in warmer conditions) and several hundred spiderlings may emerge from a single egg sac. The spiderlings will cluster around their mother for several weeks after they emerge and will tolerate each other during this stage. Once they disperse any chance meetings of the siblings will often result in one eating the other.

These spiders grow by shedding their outer skeleton (exoskeleton). This process is called ecdysis or moulting. To moult successfully they need to hang uninterrupted beneath a leaf or branch. Their colour darkens and they stop feeding a few days before moulting, and once they begin to moult they usually complete the process in about 10 minutes. They usually will not feed for about 24 hours after moulting. Males and females can be identified as they mature; males have enlarged bulbs on the ends of their pedipalps (feelers) which females lack, and males tend to have thin bodies and longer legs.

Care guide

Food: Live insects. Crickets, cockroaches, moths and flies are ideal. The food insects should be no larger than 1/3 of the size of your spider. Feeding twice a week is recommended, but young spiders will feed more often when they are growing. Remove live insects from your enclosure if your spider is not hungry.

Water: Mist spray lightly around your spider every second day – it will drink the droplets.

Enclosure: The enclosure needs to be large enough to allow your spider to shed its exoskeleton properly. An ideal enclosure should be higher than it is wide, as these spiders like to climb upwards. Jars or plastic containers make great homes for young spiders, and plastic terrariums are good for larger specimens. Add flat pieces of bark to your enclosure to give the spider something to climb on and hide behind. Ensure the enclosure is not placed in direct sunlight as this may cause it to overheat. Make sure there is plenty of ventilation in your enclosure; fly wire mesh is ideal, but ensure there are no gaps which allow the spider to get out.

Temperature: This species will thrive at 24 – 26 degrees C, but will tolerate 12 – 24 degrees and have a slower growth rate.

Life span: 2-3 years.

Handling: Direct handling is not recommended. Although these spiders are not dangerously venomous and are quite timid, adults do have large fangs and could give a painful bite. If you need to transfer them, they can be easily guided into a jar or plastic container.

Reproduction: Adult males will mate with adult females at any time of the year in captivity. Pairing them requires a large enough enclosure to allow the male to be introduced well away from the female so that he can make his own way towards her. Cramped conditions may lead to the female consuming the male before mating occurs. The male will need to climb under the female to mate using his pedipalps. The female will produce an egg sac after mating, the time between mating and egg deposition can vary dependant on the age of the female, her condition and the temperature she is being kept at. This period can be from a few weeks to months. Females can produce up to four egg sacs from a single mating.

Common issues: Due to their flattened bodies and fast speed, these spiders are excellent escape artists! Ensure there are no gaps around the lid or doors of your enclosure, and take care not to allow your spider to run out when opening it.
